Peter Jančovič

Objectives

To understand

- Application of HMMs for automatic speech recognition
- HMM assumption

Pattern Recognition

- Suppose we have a finite number of classes, w_1, \dots, w_C and the goal is to decide which class has given rise to the measurement x
- The probability of the class w given the measurement x is called **posterior probability of the class w** – denoted by $P(w|x)$

Bayes' Theorem

- The form of **Bayes' Theorem** which we need for pattern recognition is:

Assignment Project Exam Help

Class-

Prior probability

<https://eduassistpro.github.io/>

$$P(w|x) = \frac{p(x|w)P(w)}{p(x)}$$

Add WeChat edu_assist_pro

Posterior probability

Automatic Speech Recognition

- Given a sequence of acoustic feature vectors

$$Y = \{y_1, \dots, y_T\}$$

we want to find the sequence of words

$$W = \{w_1, \dots,$$

such that the <https://eduassistpro.github.io/>

$$P(W / Y)$$

is maximized.

- If $M = \{M_1, \dots, M_K\}$ is the sequence of HMMs which represents W , then $P(W / Y) = P(M / Y)$

Bayes' Theorem

- Computation of the probability $P(M / Y)$ is made possible using **Bayes' Theorem**

$$P(W | Y) = \frac{p(Y | W)P(W)}{p(Y)}$$

<https://eduassistpro.github.io/>

- $P(W)$ is the “language model probability”
- $p(Y / W)$ is the “acoustic model probability”

Mathematical Modelling

- Mathematical modelling for speech recognition
- Two conflicting requirements:
 - Faithful model of human speech production/perception
 - Mathematically Useful
- HMMs are one of the best

se at the

‘Divide and Conquer’

- One possible approach to ASR is sequential ‘divide and conquer’, e.g.
 - classify speech vectors as ‘acoustic features’
 - classify sequences of acoustic features as phonemes
 - classify sequences of phonemes as words
 - classify sequences of words ...

DISASTER!!

Delayed Decision Making

- Another name for this might be non-recoverable error propagation!
- Better to avoid decisions until all sources of information are available. Then perform classification as a single process - delayed decision making
- Delayed Decision Making underlies HMM success

The ‘HMM Compromise’

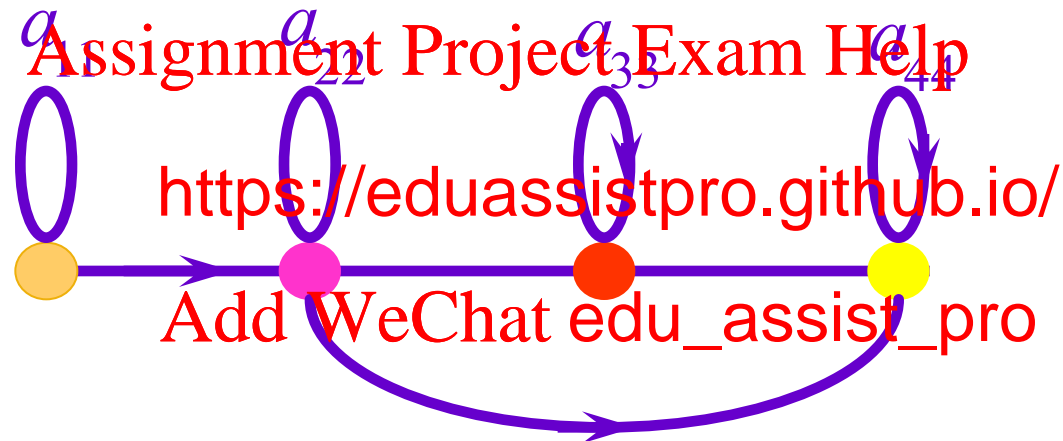

Assume that :

- A spoken utterance is a time-varying sequence which moves through a sequence of ‘segments’
– (yes) <https://eduassistpro.github.io/>
- Underlying s is constant w.r.t time – (no!)
<https://eduassistpro.github.io/>
Add WeChat edu_assist_pro
- Durations of segments vary – (yes)
- All variations between different realizations of the segments are random – (no!)

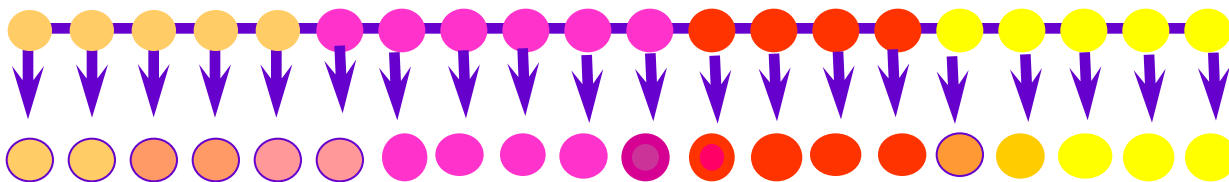

Hidden Markov Model

- In a **hidden** Markov model, the relationship between the observation sequence and the state sequence is ambiguous.

$X = \{x_t\}$

$Y = \{y_t\}$

Hidden Markov Models

A HMM consists of

- A set of states $S = \{s_1, \dots, s_N\}$
- A state transition probability matrix $A = [a_{ij}]_{i,j=1,\dots,N}$,

where $a_{ij} = \text{Prob}(s_t = s_j \mid s_{t-1} = s_i)$

- For each state s_i , a set of possible observations $O = \{o_1, \dots, o_M\}$

$$b_i(o) = \text{Prob}(y_t = o \mid x_t = s_i)$$

- b_i is called the **state output PDF** for state i (or the i^{th} **state output PDF**)

10 state HMM of the digit 'zero'

HMM Assumptions

- **Temporal Independence** - the observation y_t depends on the state x_t but is otherwise independent of the rest of the observation sequence $Y = \{y_t\}$!
... so, the pos t at time t is independent
<https://eduassistpro.github.io/>
- **Piecewise stationarity** - the underlying structure of speech is a sequence of stationary segments
- **Random variability** - variations from this underlying structure are random

HMM State Duration Model

- Constant segments correspond to the HMM states

- Probability of state duration D is given by

$$P_i(D) = (1 - a_{ii})a_{ii}^{(D-1)}$$

Summary

- Introduction to application of HMMs for speech recognition – HMM assumptions
